More Number Theory

Prime Numbers

- Prime numbers only have divisors of 1 and itself
  - They cannot be written as a product of other numbers
- Prime numbers are central to number theory
- Any integer $a > 1$ can be factored in a unique way as

$$a = p1^{a1} * p_2^{a2} * \ldots * p_t^{at}$$

where $p_1 < p_2 < \ldots < p_t$ are prime numbers and where each a_i is a positive integer

- This is known as the fundamental theorem of arithmetic

Fermat's Theorem

- States the following:
  - If *p* is prime and *a* is a positive integer not divisible by *p* then

$$a^{p-1} = 1 \pmod{p}$$

- Sometimes referred to as Fermat's Little Theorem
- An alternate form is:
  - If *p* is prime and *a* is a positive integer then

$$a^p = a \pmod{p}$$

- Plays an important role in public-key cryptography

Euler's Theorem

- States that for every *a* and *n* that are relatively prime:

$$a^{ø(n)} = 1(\text{mod } n)$$

- An alternative form is:

$$a^{ø(n)+1} = a(\text{mod } n)$$

- Plays an important role in public-key cryptography

Miller-Rabin Algorithm

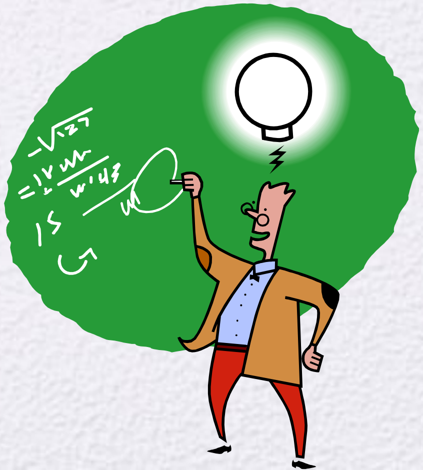
- Typically used to test a large number for primality
- Algorithm is:

TEST (n)

1. • Find integers k, q, with $k > 0$, q odd, so that $(n - 1)=2^kq$;
2. • Select a random integer a, $1 < a < n - 1$;
3. • **if** $a^q \bmod n = 1$ **then** return ("inconclusive") ;
4. • **for** $j = 0$ **to** $k - 1$ **do**
5. • **if** $(a^{2^jq} \bmod n = n - 1)$ **then** return ("inconclusive") ;
6. • return ("composite") ;

Deterministic Primality Algorithm

- Prior to 2002 there was no known method of efficiently proving the primality of very large numbers
- All of the algorithms in use produced a probabilistic result
- In 2002 Agrawal, Kayal, and Saxena developed an algorithm that efficiently determines whether a given large number is prime
  - Known as the AKS algorithm
  - Does not appear to be as efficient as the Miller-Rabin algorithm



Chinese Remainder Theorem (CRT)

- Believed to have been discovered by the Chinese mathematician Sun-Tsu in around 100 A.D.
- One of the most useful results of number theory
- Says it is possible to reconstruct integers in a certain range from their residues modulo a set of pairwise relatively prime moduli
- Can be stated in several ways

Provides a way to manipulate (potentially very large) numbers mod *M* in terms of tuples of smaller numbers

- This can be useful when *M* is 150 digits or more
- However, it is necessary to know beforehand the factorization of *M*
